Characterization of particulates in the gas exchange system of DI/SI engines

-Arun Prasath K

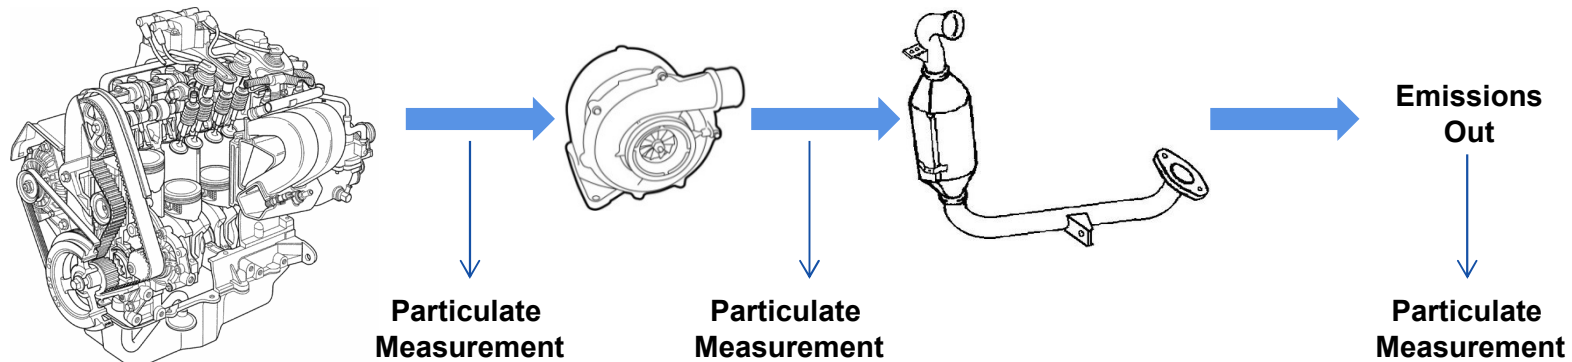

VOLVO

BorgWarner

Initial phase of the work

- Setting up the engine for experiments with particulate measurement systems
 - Fixing the measuring conditions like dilution ratio, temperature, etc.
 - Arriving at appropriate particulate measurement systems
 - Experimenting fixed load points at constant speeds
- Effect of pipe geometries (straight pipe, bends, expansion, etc.,) on particle size distribution with steady flow experiments
- Looking up the previous work done in particulate measurements and characterization

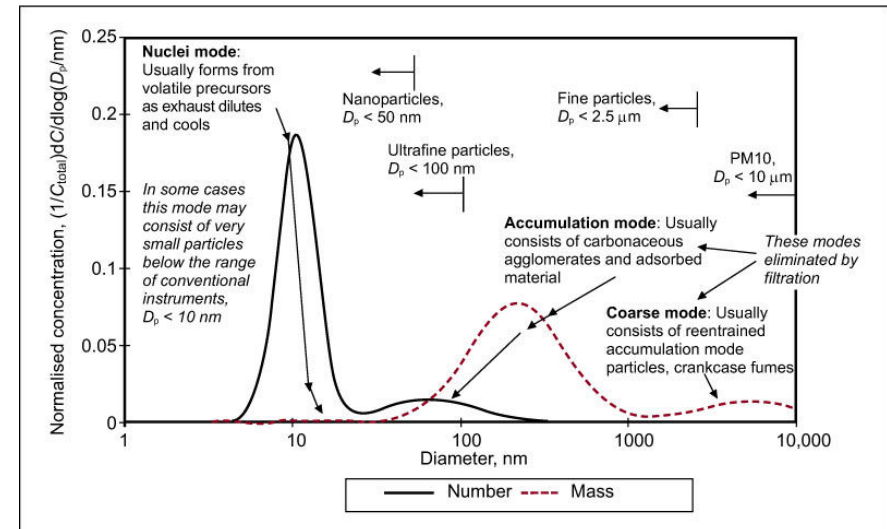

Outline of the work

- Setting up the engine for steady state load conditions
 - Use of experimental data for 1-D model generation based on engine parameters
 - Finding the independent variables for the particle number distribution
- Experiments on the engine for transient load conditions
 - Refining the 1-D model based on transient response
- Concept development and designing of agglomeration device
 - Testing of the device in steady state and transients
- 1-D model development for the agglomeration device
 - Validation and refining with actual experimental data
- Implementation of the 1-D model generated in GT power
 - Checking for the accuracy of the model

-
- The diagram shows a network of three nodes connected in a line. Each node is represented by a blue rectangle with a vertical line through its center. The first and third nodes have a grid of dots, while the middle node has three dots. Blue arrows indicate flow from left to right. Above the network is a plot of a probability distribution $P(x)$ versus x . The curve is red and peaks at $x=1$. The formula for the distribution is given as $\frac{1}{S\sqrt{2\pi x}} e^{-(\ln x - M)^2 / (2S^2)}$.
